

# Appendix I-E: Overview of Key Models and Data 

This appendix provides a detailed description of the data, modeling, geographic information system (GIS) and mapping information and tools that were used in the Final Environmental Impact Statement. Following an overview, sections E. 2 through E. 4 document the methodology for extending currently adopted jurisdictional growth targets in the Growth Targets Extended and Preferred Growth alternatives, the methodology for estimating impervious surfaces in chapter 5.6, and the transportation demand model output data.

## E.1. MODEL OVERVIEW

## I. Geographic Information Systems

The Puget Sound Regional Council uses geographic information system technology to support a variety of agency functions, including land use and transportation planning. PSRC uses the ArcGIS suite of products from ESRI in conjunction with Microsoft's SQL-Server and Access database software. Maintained data sets include transportation networks, a composite of local land use plans, environmental features, transportation capital projects from Destination 2030 (the region's adopted Metropolitan Transportation Plan) and the Regional Transportation Improvement Program, as well as a full compliment of US Census and demographic layers.

## II. INDEX - Paint the Region Analysis Tool

With the assistance of its consultants - Criterion Planners/Engineers, Inc. - the Puget Sound Regional Council customized and implemented a new sketch-planning tool called INDEX - Paint the Region. The PSRC used INDEX to conduct sensitivity tests of how the region might accommodate growth, leading to the development and analysis of growth alternatives included in this environmental impact statement.

INDEX - Paint the Region is a geographic information system sketch-planning tool that brings to the Regional Council a much finer grain of analysis than has been available in the past. It provides flexibility to construct and analyze "what if" scenarios for how growth can be distributed in the region. With INDEX, regional growth scenarios can be quickly "painted," then analyzed and compared through the generation of 17 environmental, land use, demographic, and transportation indicators. Indicators are available at a variety of geographic levels in numeric and map forms. Between December 2004 and Summer 2005, the PSRC developed and analyzed a range of eight scenarios, with the goal of producing a broad and distinct set of regional growth alternatives to be assessed for social, economic and environmental impacts in the State Environmental Policy Act project environmental impact statement.

The alternatives describe different ways in which the region might accommodate future growth through the distribution of population and employment in different parts of the region. Please see Chapter 4 - Definition of Alternatives for a complete description of the regional growth alternatives.

These alternatives were then "painted" in the PSRC geographic information system using the INDEX analysis tool. The starting point in INDEX is a base land use GIS "canvas" consisting of a layer of 150 square meter ( 5.5 acre) grid cells covering the entire central Puget Sound region. These cells are populated with 2000 base year demographic data developed for the new PSRC Land Use and Demographic model, UrbanSim. This UrbanSim database also contained detailed demographic attributes at the grid cell level necessary to run the Regional Travel Demand Model. Among these attribute data, grid cells were encoded with one of 26 land-use classes derived from UrbanSim planned land use categories and the PSRC Future Land Use database (a compilation of locally adopted comprehensive plans). The GIS also contains additional geographic and environmental attribute data to provide context and inputs for various INDEX indicators. To create a growth scenario, the user paints grid cells with the desired land-use class ("paint chip"). The paint chips apply default population and employment values to represent the "end state" condition of the cell.

The painting of the alternatives began with all of the region's grid cells encoded with future land use designations drawn from current local comprehensive plans, and populated with base year 2000 population and employment. Staff did not allocate any growth to grid cells painted with the following land use designations: Agriculture, Critical Areas, Forest, Government, Parks and Open Space, Resource Extraction, Right of Way, or Tribal.

First, staff "built out" the local plan designations by adding the specified population and employment growth to grid cells based on the maximum carrying capacity defined by the available land use designations. This was accomplished by using Microsoft Access to select grid cells with specified land use categories within particular jurisdictions. These queries determined which cells had additional capacity according to a comparison of base population or employment data and maximum values for each land use classification. Staff then added population and employment to the selected cells through update queries in the Access database.

Staff typically first built out existing mixed use-designations, followed by higher intensity residential and commercial land uses. Staff found that these designations were generally clustered within urban centers or activity nodes within jurisdictions, and along major transportation corridors. When growth still remained to be painted, it was then assigned to the lowest density residential classifications in a jurisdiction - generally to cells that contained no base year population.

If additional growth remained, or when initially presented with a large amount of growth to assign, staff looked first in a jurisdiction for designated regional growth centers, local urban centers, town centers, and other activity areas. Grid cells within these designated areas were then "repainted" with higher-density land use classifications, which carried with them higher default population and employment values. For example, lowintensity commercial classifications might be repainted at the next higher commercial intensity, or lowerintensity residential, or mixed use areas redesignated with higher density mixed-use categories. This enabled staff to allocate all of a jurisdiction's growth in a more focused manner than through more general queries that would populate grid cells across an entire jurisdiction or regional geography. In this manner, staff was able to assign a precise amount of assigned growth to each municipality and broad classes of regional geography.

Once the entire canvas was painted with the desired land uses, the INDEX tool was run, generating indicators to provide a better understanding of possible long-term benefits and impacts of the choices represented in the scenario. The scenarios that were created and tested through this process were evaluated and compared based on indicator values and results, and led to the development of the alternatives analyzed in this Final environmental impact statement.

A table documenting the resulting population and employment distribution at the city level for each alternative appears in the following section of this appendix (section E.2). These distributions were used as technical inputs to the Regional Council's EMPAL/DRAM land use and Regional Transportation Demand models. Please see section III below.

The following table describes INDEX indicators that were available for environmental analysis.

| INDEX - Indicators for VISION 2040 Analysis |  |  |  |
| :---: | :---: | :---: | :---: |
| Indicator | Definition | Units | Geographies <br> Reported |
| Demographics |  |  |  |
| Population* | Total number of residents in use-defined study area. | Residents | Region <br> UGA <br> Rural <br> County <br> KC Subarea |
| Employment* | Total number of employees in user-defined study area. | Employees | Region <br> UGA <br> Rural <br> County <br> KC Subarea |
| Population Density | Total residents per acre of residential land. | Residents per residential acre | Region <br> UGA <br> Rural <br> County <br> KC Subarea |
| Gross Population Density* | Total residents per gross study area acre. | Residents per gross acre | Region <br> UGA <br> Rural <br> County <br> KC Subarea |
| Housing |  |  |  |
| Dwelling Density* | Dwelling units per acre of land designated for residential use. | Dwelling units per residential acre | Region <br> UGA <br> Rural <br> County <br> KC Subarea |
| Gross Dwelling Density | Dwelling units per gross acre. | Dwelling units per gross acre | Region <br> UGA <br> Rural <br> County <br> KC Subarea |
| Population Adjacency to Amenities | Percent of residents within user-defined linear distance of user-designated amenities (e.g. school, community center, parks, etc.). PSRC defined distance as 1,320 feet (1/4 mile). | Percent (\%) | Region UGA <br> County UGA |
| Population Adjacency to Transit | Percent of residents dwelling within user-defined linear distance of transit routes. PSRC defined distance as 1,320 feet ( $1 / 4$ mile). | Percent (\%) | Region UGA County UGA |

| INDEX - Indicators for VISION 2040 Analysis |  |  |  |
| :---: | :---: | :---: | :---: |
| Indicator | Definition | Units | Geographies Reported |
| Employment |  |  |  |
| Employment to Dwelling Balance | Total number of jobs divided by number of dwelling units. | Jobs per dwelling unit | Region <br> UGA <br> Rural <br> County <br> KC Subarea |
| Employment Density* | Number of employees per gross acre. | Employees per gross acre | Region <br> UGA <br> Rural <br> County <br> KC Subarea |
| Employment Density* | Number of employees per acre of land designated for employment uses. | Employees per gross acre | Region <br> UGA <br> Rural <br> County <br> KC Subarea |
| Employment Adjacency to Transit | Percent of employees within user-defined linear distance of transit routes. PSRC defined distance as 1,320 feet (1/4 mile). | Percent (\%) | Region UGA <br> County UGA |
| Environment |  |  |  |
| Wastewater Generation* | Total study area wastewater in gallons, calculated by number of residents and co-efficient in gallons per capita. | Gallons per day | Region <br> UGA <br> Rural <br> County <br> KC Subarea |
| Solid Waste Generation* | Total study area solid waste generation in pounds, calculated by number of residents and co-efficient in Ibs/capita. | Pounds per day | Region <br> UGA <br> Rural <br> County <br> KC Subarea |
| Stormwater Runoff | Average annual runoff depth in cubic feet/acre/year. Influenced by underlying soil type and impervious surfaces. (Note: uses US EPA SGWATER methodology.) | Cubic feet per acre per year | Region <br> UGA <br> Rural <br> County <br> KC Subarea |

[^0]| INDEX - Indicators for VISION 2040 Analysis |  |  |  |
| :---: | :---: | :---: | :---: |
| Indicator | Definition | Units | Geographies Reported |
| Nonpoint Pollution | Average annual combined NPS pollution in kg/acre/year for three pollutants (suspended solids, nitrogen compounds, and phosphorus compounds) based on imperviousness and stormwater runoff volume. (Note: uses US EPA SGWATER methodology.) | Kilograms per acre per year | Region <br> UGA <br> Rural <br> County <br> KC Subarea |
| Imperviousness | Amount of impervious surface as percent of total land area. Standard impervious surface values assumed by land use class, derived from national and City of Olympia research. | Percent (\%) | Region UGA County UGA |

## III. Socioeconomic Forecasts

The Puget Sound Regional Council provided a socioeconomic forecast database for the region for the environmental analysis, using the inputs and outputs of its current econometric and land use forecasting models. Forecasts are produced in a two-step process, first at the regional level, then sub-regional (county and zone) level, using two separate modeling systems. The key demographic variables produced by both processes are forecasts of population, households, housing units and employment, to ensure consistency between the two modeling procedures.

For the regional model database, annual estimates and forecasts were available from approximately 1970 to 2040. Additional detail in the database included income earned, households by type, and population by age grouping.

At the sub-regional level, forecasts are limited to the years 2010, 2020, and 2030, along with a comparable base year of 2000. The data was summarized by county (and in King county's case by county subarea) and by forecast analysis zone. Detail included separation of population into group quarter versus household population, households by income level, and total employment by PSRC-defined major employment sectors.

The following sections document the models used to generate the socioeconomic forecasts for this study in more depth.

## A. Current Regional Economic and Demographic Model: PSEF Model

Since 1980, the Regional Council has used a regional econometric model as the first part of a two-part forecasting process. The model produces forecasts for the region as a whole, which then serve as the regional control totals for the separate sub-county model that allocates population, household, and employment forecasts to specific zones. The resulting regional and small-area forecasts support comprehensive land use and transportation planning undertaken by the Regional Council, and related planning activities conducted by local jurisdictions within the region.

The regional forecasting application that was used from 1980 until May 2002 was the STEP (Synchronized Translator of Econometric Projections) model, with updates occurring every 3-4 years. In 2005, however, PSRC entered into a consultant contract to replace the STEP model with the Puget Sound Economic Forecaster (PSEF) Model, which is better suited to work with the more limited amount of data available since the conversion of economic data from the Standard Industrial Classification (SIC) codes to the North American Industrial Classification Systems (NAICS).

Like STEP, the PSEF model operates conceptually as an economic base model, where the performance of base industries, or those that export outside of the region, determines the performance of the non-basic sector industries. Within this structure, a series of equations are used to forecast regional economic conditions in broad categories of income, employment/labor force, and population/households. Also required are input forecasts of the U.S. economy, and the assembly of substantial trend data, in order to accurately estimate economic and demographic relationships in the regional economy, and how it relates to national trends.

Note that forecasts of population are done in a different manner than the official population forecasts produced by the Washington State Office of Financial Management for growth management planning work by the counties. The econometric modeling structure relies more on the performance of the economy to determine the amount of net population migration that occurs, along with what has been seen as consistent birth and death rates in the region, although the results are carefully reviewed for consistency.

Updated regional forecasts through 2040 were available for use in the VISION 2040technical analysis. In the first quarter of 2006, PSRC will have the full results of the PSEF-based forecasts posted on the agency website, along with a final report.

## B. Land Use Models: EMPAL and DRAM

Similar to the STEP model, PSRC has historically used the EMPAL (Employment Allocation Model) and DRAM (Disaggregate Residential Allocation Model) gravity models to estimate jobs, population, and households for each of 219 Forecast Analysis Zones (FAZs) in the region. From these zone totals, countylevel forecasts are derived, as well as inputs to the travel demand model.

Since the initial use of EMPAL/DRAM in the early 1980s, a number of key assumptions and inherent limitations have been recognized in their use. The sub-county forecast results are limited to the FAZ level of geography, so forecasts by cities or other basic geographies cannot be done within the model structure. The EMPAL and DRAM models are limited to roughly 200 zones, making further subdivision of zones a problem. Land use inputs are not implicit to the model, so the impact of comprehensive plans or other policy changes must be replicated indirectly, by either manually adjusting the "attractiveness" of a zone to further development, or overriding model results with pre-determined job targets. Furthermore, the use of such adjustments and targets limits the ability of the models to be used in sensitivity analyses. (Note that to be consistent with the regional model forecasts, and input needs for the travel demand model, job forecasts from EMPAL are not directly comparable to the Covered Employment estimates the Regional Council produces.)

Like the STEP model, PSRC has initiated work to upgrade its land use models. In 2003 PSRC entered into a Memorandum of Understanding with the University of Washington's Center for Urban Simulation and Policy Analysis (CUSPA) to implement UrbanSim as the Regional Council's land use model, replacing the EMPAL/DRAM models. This decision was a response to the increasing demands placed on the agency's land use models, both in terms of supporting the travel demand model, but also the desires of PSRC's boards and planning staff to better analyze policy options, including the connections between land use and travel demand.

The complexity of UrbanSim, however, has resulted in the need for additional testing and validation of the model results, before it can be used with confidence as a technical tool. Although the current schedule calls for UrbanSim to eventually become the PSRC's new land use model, the need for an updated forecast prior to that has led to the use of the EMPAL/DRAM models for the 2006 Small Area Forecasts, planned for release in Spring 2006. The current sub-regional forecasts from the EMPAL/DRAM models were released in January 2003, and can be found at http://www.psrc.org/datapubs/data/forecasts.htm on the agency website.

## C. Representing VISION 2040AIternatives in PSRC Models

The INDEX analysis tool, while effective for sketching and visualizing future growth alternatives, was designed with limited ability to produce details on the future year population and employment data. Therefore, in order to convert the distribution of population and employment in each of the VISION 2040 alternatives as painted using the INDEX tool to inputs that would be compatible with the Regional Travel Demand Model, PSRC supplemented the INDEX data with elements of the most current EMPAL/DRAM-based Small Area Forecasts. Below is a comparison of the base data provided by INDEX, and the detailed data provided by EMPAL/DRAM or needed for the Regional Travel Demand Model:

| Index Analysis Tool <br> Base Data Categories | EMPALIDRAM \& Regional Travel Demand <br> Model Detailed Data Variables |
| :--- | :--- |
| Total Population | Population separated into: <br> $-\quad$ Household Population <br> $-\quad$ Group Quarters Population |
| Housing Units | Households by Income Quartile: |

| Index Analysis Tool <br> Base Data Categories | EMPALIDRAM \& Regional Travel Demand <br> Model Detailed Data Variables |
| :--- | :--- |
|  | $-\quad$ Low Income Households |
|  | $-\quad$ Lower Middle Income Households |
|  | $-\quad$ Upper Middle Income Households |
|  | $-\quad$ Upper Income Households |

The following procedure was used to develop the detailed data necessary to run the Regional Travel Demand Model for each VISION 2040 alternative:

- Convert the INDEX base data geography from gridcells and cities to Forecast Analysis Zones (FAZs): The EMPAL/DRAM models are zonal-based, and limited structurally to the 219 zones within the central Puget Sound Region. The first step was to calculate base year 2000 and future year 2040 population, housing and employment totals for each of the 219 FAZs for each alternative using the INDEX base grid cell and city data. Then, using PSRC's year 2000
- Expand the INDEX 2000 base year data into detailed data variables: As noted earlier, 2000 base year data used in INDEX was derived from a more detailed year 2000 database prepared for the UrbanSim model. After calculating overall population, housing and employment totals for each FAZ from the INDEX data, PSRC staff re-applied original UrbanSim data detail to produce FAZ level data compatible with the Regional Travel Demand Model.
- Apply the growth projected in PSRC's current Small Area Forecasts: The most recent EMPAL/DRAM forecasts from 2003 have both year 2000 and year 2030 forecasts by FAZ for each of the detailed data variables necessary to run the Regional Travel Demand Model. Using both the growth rate and the year 2030 forecast for each variable, 2040 totals painted using INDEX were disaggregated within each FAZ. For example, if the proportion of Low Income Quartile households in a particular FAZ decreased between 2000 and 2030, that same proportional shift was applied to the year 2040 FAZ totals derived from the original INDEX data.
- Balance the preliminary estimates with the regional forecasts for 2040: As noted earlier, PSRC's forecast process is top-down, with the regional demographic and economic forecasts determined first, and then allocated to a sub-regional geography. To control to these forecasts, a factoring process adjusted each alternative's INDEX-based 2040 FAZ-level detailed data so that the alternatives, as modeled, would also match the regional forecasts.

## IV. Regional Travel Demand Model

PSRC provided the consultant base year travel demand model data for the base year 2000, along with travel demand forecasts for the years 2010, 2020, 2030, and 2040. Performance indicators will include: vehicle miles traveled, average travel speed, hours of delay, percentage of regional roadway network congested (AM, PM, Off Peak - Freeways, Regional Arterials, Overall), and regional travel mode choice (SOV, Carpool, Transit). The data will be summarized at the subregional level by county (and in King county's case by county subarea), by transportation analysis zone (TAZ).

The travel demand model currently employs the traditional four-step modeling process (trip generation, trip distribution, mode choice, assignment). A vehicle availability model and a time-of-day model are included. Five time periods are modeled overall (two time period for transit trips) with seven vehicle types (Single Occupant Vehicle [SOV], High Occupancy Vehicle with 2 occupants [HOV2], High Occupancy Vehicle with 3
or more occupants [HOV3+], Vanpool, Light Truck, Medium Truck, Heavy Truck) as well as bus, ferry, rail and non-motorized modes. Resulting performance measures include daily and peak period traffic volumes, congested speeds/times, mode splits, origins/destinations, trips by purpose and Volume-to-Capacity ratios among others. EMME/2 is the modeling software used by PSRC to run the regional travel demand model.

The travel model uses outputs from the Land Use model (EMPAL/DRAM) as demographic \& employment inputs. These are combined with travel survey data to generate trips used as demand. The trips are paired up in the trip distribution process (destination choice model for work-trips, gravity model for non-work trips). The mode choice model determines the mode of travel for each trip and the time-of-day model allocates trips to the five time periods. Finally the assignment process uses shortest path algorithms iteratively to load the networks.

Recent improvements to the travel model were recommended and implemented by Cambridge Systematics from 2001 to 2003. Some of these improvements include: updated trip generation rates, introduction of a truck model, addition of vanpool trips, increase of time-periods to 5 , more special generators, new volume delay functions, a new parking cost model and updated mode choice factors using local travel surveys. Cambridge's model update report can be found at http://www.psrc.org/datapubs/pubs/modeltravel.pdf.

Future improvements include adding a non-motorized network for bike trips, expanding the four county networks to include four external counties (skeletal networks/zone systems for Island, Mason, Skagit \& Thurston counties), upgrading the land use inputs with the UrbanSim model and integrating the highway and transit networks with a GIS-based geodatabase.

Tables documenting the results of modeled trip generation for each VISION 2040 FEIS alternative appear at the end of this appendix.

Other publications regarding PSRC's travel models can be found on the agency's web site at http://www.psrc.org/datapubs/pubs/publist//publist models.htm. Information about EMME/2 (the modeling software) can be obtained at http://www.inro.ca/products/e2 products.html.

## V. Regional Air Quality Model

The central Puget Sound region is currently designated by the U.S. Environmental Protection Agency as a maintenance area for particulate matter less than 10 microns in diameter $\left(\mathrm{PM}_{10}\right)$ and carbon monoxide (CO). The region was formerly designated as a maintenance area for ground level ozone $\left(\mathrm{O}_{3}\right)$, but under EPA's new ozone standard is now designated an attainment area for that pollutant.

The process the Regional Council uses for estimating future regional emissions of these pollutants involves the integration of the Regional Council's land use and travel demand modeling with EPA's emissions factor model (MOBILE6.2 vehicle emissions modeling software).

Emissions are calculated on an individual transportation demand model link basis, based on forecast vehicle miles traveled and speed of each link. This calculation is performed separately for each of five time periods (a.m. peak, midday, p.m. peak, evening and nighttime). Emissions are calculated for both intrazonal and interzonal trips. The calculated emissions of individual links are then summed for each of the five time periods, which in turn are summed for the total daily emissions in each maintenance area.

Air quality emissions estimates were prepared for each of the alternatives that were developed for the environmental impact statement.

## E.2. METHODOLOGY FOR DEVELOPING THE PREFERRED GROWTH AND GROWTH TARGETS EXTENDED ALTERNATIVES

This section explains the methodology used to develop the population and employment distribution analyzed in the Preferred Growth and Growth Targets Extended alternatives.

As noted in the Overview section, all of the alternatives were painted in an identical manner using the INDEX model. That is, each of the 5.5 -acre grid cells were encoded with one of the 26 land-use classes (known as paint chips). These paint chips applied default population and employment values to represent the end state condition of the cell, that is, the number of people and jobs in that call in the year 2040. The final painting step involved adjusting these land use classifications or default values to match the growth distribution alternative allocations, as suballocated to regional geographies, by county.

Two of the alternatives required additional technical methodology to determine how to change the default values - these were the Growth Targets Extended and the Preferred Growth alternatives. While this additional work affected the numbers painted into each cell, the ultimate painting of the cells in INDEX involved the identical land use classes and adjustments of default values.

## A. Overview - Growth Targets Extended

The Growth Targets Extended Alternative represents one interpretation of where the region's residents and jobs will be located in 2040, based on two key assumptions. The first is that population growth targets that have been adopted by each of the cities and counties will be achieved by either 2022 or 2025, depending on the jurisdiction. Secondly, population growth beyond the year 2025 will locate relative to the proportion of the region's 2025 population that each jurisdiction would represent after achieving the growth targets. This is a representation of the regional population and employment development patterns that would result from achieving 2022 - 2025 growth targets, reinforced and intensified through year 2040 forecasted population and employment. For example, City A adds 20,000 people by 2025 to achieve its growth target of 140,000 total people. The 140,000 people represent 3 percent of the regional 2025 total population figure. City A then receives 3 percent of the additional population growth from 2025 to 2040 under the Growth Targets Extended Alternative.

The methodology for allocating employment differed slightly from that of population. Both methods are described below:

## Population - Growth Targets Extended

Step 1: Adjust Base Year Population: Three out of the four counties used 2000 as the base year for setting their targets, except for Snohomish, which used 2002. To remain consistent among the counties, Snohomish's 2002 base year had to be adjusted to 2000 . The most viable option was to use Census 2000 population figures as a substitution for Snohomish County's base.

Step 2: Standardize Population Targets: Kitsap and Snohomish counties had growth targets for 2025, while King and Pierce adopted targets for 2022. The targets had to be adjusted so each county's numbers represented the year 2025. To account for the discrepancy, King and Pierce County's targets were grown from 2022 to 2025 by applying the average annual increase in the growth target between 2000-2022 for the additional three years.

Step 3: Determine City/Unincorporated areas' Share of Regional Target Total: Once all the target years were set to 2025 , the regional target total was calculated by adding up the targets from the four counties. The share that each city/unincorporated area held of the regional target was then calculated by dividing the city/unincorporated areas' target by the regional population target total.

Step 4: Distribute Regional Forecast Change from 2025 to 2040: Using the calculated population share for each city/unincorporated area, the change between the 2025 regional population target total and the 2040 regional forecasted population total $(705,100)$ was distributed. The final 2040 estimate, then, is the sum of the assumed 2025 target plus this additional assumed growth from 2025 to 2040.

## Employment - Growth Targets Extended

Step 1: Standardize Base Year Employment: Only two of the four counties, King and Snohomish, have set job growth targets. Because of this, Kitsap and Pierce did not have 2000 base year employment numbers. To create a standardized base year, staff used the annual PSRC job estimates, produced from the Washington State Department of Employment Security's Covered Employment data set. City-level job estimates for 2000 were adjusted to represent all jobs (not just employment covered under ESD's reporting requirements) and used as the base for all jurisdictions.

Step 2: Create Comparable Year 2020 Proxy Employment Targets and Percentages: To create proxy employment targets for jurisdictions in Kitsap and Pierce Counties, staff reviewed both the proportion of all county jobs each jurisdiction had in 2004, and the overall job growth trends from 1995 to 2004. These inputs were used to estimate the proportion of county jobs each jurisdiction would contain by 2020. Since King and Snohomish Counties have adopted job targets, these were used to produce the county-proportion figures for those jurisdictions.

Step 3: Allocate Forecast Year 2020 Jobs by County to the individual jurisdictions: So that all county proxy job targets would be consistent with a single regional employment number, the current PSRC job forecasts for each county were allocated to each jurisdiction, consistent with the percentages calculated in Step 2. For example, City B in Snohomish County would account for 30 percent of the county employment after achieving its targeted year 2025 job number. Using the PSRC Small Area Forecasts for Snohomish County, it is estimated that the county will contain 300,000 jobs in the year 2020. City B would have a year 2020 estimate of 90,000 jobs.

Step 4: Determine City/Unincorporated areas' Share of Regional Target Total: Once the year 2020 forecast employment was allocated to each jurisdiction, the share that each city/unincorporated area held of the regional figure was then calculated, similar to the year 2025 population data.

Step 5: Distribute Regional Forecast Change from 2020 to 2040: Using the calculated employment share for each city/unincorporated area, the change between the 2020 regional employment target total and the 2040 regional forecasted employment total $(793,600)$ was distributed. The sum of the 2020 job estimate, and the additional growth from 2020-2040, were summed to arrive at the overall jurisdictional job estimate for the year 2040.

## B. Overview - Preferred Growth Alternative

The following general rules were used for painting the preliminary preferred growth alternative:
Step 1: Consult Reference Tools: There are three facets of this step: (a) development capacity, (b) land use mapping, and (c) 2040 small area forecasts.

- Development Capacity: Consult evaluation of theoretical development capacity - determined by comparing theoretical buildout of current generalized land use classifications to existing base year 2000 population and employment. Calculations will be made for capacity within $1 / 4$-mile buffers of Regional Growth Center boundaries, for individual cities, and for regional geographies at the county level. This will provide a reference tool to help to determine what relative proportions of growth might be directed to a central node or Regional Growth Center area, to higher intensity mixed use classifications versus single purpose classifications, and the amount directed to the rest of the city or regional geography. After a determination is made, document the decision on a relevant preferred growth alternative documentation worksheet. Each county will have an overall county notes worksheet, as well as a worksheet documenting decisions and any relevant issues for each regional geography.
- Land Use Map: Refer to maps of various scales depicting the region and subregions painted with Index Land Use classifications. These maps will provide a visual reference for the painter. Note any overall conclusions on the relevant county or regional geography log sheet.
- 2040 Small Area Forecasts: After painting, consider overall Population and Employment levels by Forecast Analysis Zones and Transportation Analysis Zones. Consider the Technical Advisory Committee (a group of local government staff formed to assist in the development of the preferred growth alternative) recommendations for Rural and Unincorporated Urban Growth Area Transportation Analysis Zones and Transportation Analysis Zones that are most likely to develop.
- Locally adopted population allocations (Growth Targets): Refer to local adopted population targets and, where they exist, adopted employment targets. These targets, which are set at the city and other area levels, provided an important reference point to ensure that the distributions to a regional geography were within scale.

## Step 2: Consider Growth Management Policy Board Policy Direction for Developing the Preferred Growth Alternative by Regional Geography:

- Population in the Preferred Growth Alternative, adopted October 12, 2006: emphasize Metropolitan and Core Suburban cities as primary places for population concentrations - and in particular Regional Growth Center areas; increase the population role played by Larger Suburban cities in 2040, emphasizing growth in subregional centers; maintain the current role - and slightly reduce the planned share - of Smaller Suburban cities in accommodating population growth, emphasizing healthy smaller subregional and town centers; maintain the current population role of Unincorporated Urban Growth Areas, focusing first on existing highly urbanized areas, particularly within areas affiliated with incorporated cities as potential annexation areas; minimize population growth within Rural Areas, commensurate with existing and desired rural character.

When painting the Preferred Growth Alternative, employ the following general rules:

- Start with Mixed Use classifications - higher intensity to lower intensity.
- Move to single-purpose Residential classifications - higher intensity to lower intensity. Avoid overpainting lowest intensity single family residential classification (Index Land Use ID \#13).
- Place remainder in grid cells coded Mixed Use Other (Index Land Use ID \#30).
- Do not allocate additional population to grid cells determined to be undevelopable: Forest, GovMilitary, Parks \& Open Space, Right of Way, Resource Extraction, Tribal, Critical Environmental Area, Agriculture (Index Land Use ID \#s 5, 6, 12, 17, 18, 19, 20, 21).
- Employment in the PGA, adopted October 12, 2006: Continue current policy for employment, emphasizing a concentrated regional pattern with a focus on Regional Growth Centers in Metropolitan and Core Suburban cities, particularly outside of King County; increase the regional share of employment in Snohomish, Pierce and Kitsap counties; direct a somewhat smaller overall regional share of employment in Metropolitan Cities when compared to current employment targets and local plans, and within the Metropolitan Cities geography a greater emphasis on job growth in Kitsap, Pierce and Snohomish counties; increase the employment role played by Larger Suburban cities in 2040, emphasizing growth in locally designated subregional centers; slightly decrease the overall regional share of planned jobs in Smaller Suburban Cities in all counties, while emphasizing healthy smaller locally designated subregional and town centers, and their role supporting surrounding unincorporated urban and rural areas; maintain or slightly increase the employment role of Unincorporated Urban Growth Areas, focusing on existing highly urbanized and commercial and industrial areas, with some additional growth to support growing residential communities; maintain the employment role presently played by Rural Areas, commensurate with rural character and overall residential population levels in the working Preferred Growth Alternative.

When painting the Preferred Growth Alternative, employ the following general rules:

- Start with Commercial classifications - higher intensity to lower intensity. Avoid overpainting highest intensity commercial classification (Index Land Use ID \#s 3 \& 4), and in particular Industrial grid cells (Index Land Use ID \#7).
- Move to Mixed Use classifications - higher intensity to lower intensity.
- Place remainder in grid cells coded Mixed Use Other (Index Land Use ID \#30).
- Do not allocate additional employment to grid cells determined to be undevelopable: Forest, Gov-Military, Parks \& Open Space, Right of Way, Resource Extraction, Tribal, Critical Environmental Area, Agriculture (Index Land Use ID \#s 5, 6, 12, 17, 18, 19, 20, 21).

Step 3: Paint by Regional Geography, by County: In each county, growth will generally be distributed by regional geographic class, or by a subset of a regional geographic class as defined below. Local conditions and characteristics of jurisdictions in regional geographies will be considered in each county to modify approach as appropriate.

- Metropolitan Cities
- Determine proportions of allocation to be assigned to $1 / 4$ mile buffered RGC areas and to the balance of the regional geography by consulting Development Capacity assessment, INDEX planned land use maps and locally adopted targets and land use designations.
- Record allocations - along with any geography-specific observations - on log sheet.
- Select grid cells in $1 / 4$ mile buffered RGC areas within regional geography.
- Query buffered RGC cells in the order described above for Population and Employment distribution.
- If necessary, repaint RGC and buffer areas with new land use classifications to accommodate share of allocation.
- Distribute balance to rest of regional geography (consult reference tools).
- Core Suburban Cities
- Determine proportions of allocation to be assigned to $1 / 4$ mile buffered RGC areas and to the balance of the regional geography by consulting Development Capacity assessment, INDEX planned land use maps and locally adopted targets and land use designations.
- Record allocations - along with any geography-specific observations - on log sheet.
- Select grid cells in $1 / 4$ mile buffered RGC areas within regional geography.
- Query buffered RGC cells in the order described above for Population and Employment distribution.
- If necessary, repaint RGC and buffer areas with new land use classifications if necessary to accommodate share of allocation.
- Distribute balance to rest of regional geography (consult reference tools).
- Larger Suburban Cities
- Determine proportions of allocation to be assigned to Town Center or City Center areas (derived from local comprehensive plans) and to the balance of the regional geography by consulting Development Capacity assessment, INDEX planned land use maps and locally adopted targets and land use designations.
- Record allocations - along with any geography-specific observations - on log sheet.
- Select grid cells within Center areas in the regional geography in the order described above for Population and Employment distribution.
- If necessary, repaint City or Town Center areas with new land use classifications to accommodate share of allocation.
- Distribute balance to rest of regional geography (consult reference tools).
- Smaller Suburban Cities
- Determine proportions of allocation to be assigned to subclasses A (cities within contiguous UGA) B (very small residential towns) and C (freestanding cities) by applying the current planned share of 2000 - 2025 change for the sub-class compared to the overall change of the Smaller Suburban City regional geography in the county. Determine whether planned share to subclass A is adequate, or should be increased somewhat to reflect county-specific conditions and GMPB policy direction.
- Consult Development Capacity assessment, INDEX planned land use maps and locally adopted targets and land use designations, additional guidance to determine proportion of allocation to be assigned to Mixed Use areas within each sub-class.
- Record allocations - along with any geography-specific observations - on log sheet.
- Select grid cells within the regional geography sub-class in the order described above for Population and Employment distribution.
- If necessary, identify City or Town Center areas and repaint with new land use classifications to accommodate share of allocation.
- Distribute balance to rest of regional geography subclass (consult reference tools).
- Unincorporated Urban Growth Areas
- Determine proportions of allocation to be assigned to Affiliated and Unaffiliated Urban Growth Areas by applying the current planned share of 2000-2025 change for the sub-class compared to the overall change of the regional geography. Determine whether planned share to Affiliated areas is adequate, or should be increased somewhat to reflect GMPB policy direction.
- Determine proportions of allocation to be assigned to Mixed Use areas by consulting INDEX planned land use maps, and locally adopted targets and land use designations.
- Record allocations - along with any geography-specific observations - on log sheet.
- Select grid cells within the Affiliated UGA sub-class in the order described above for Population and Employment distribution.
- If necessary, identify Activity Center areas within Affiliated UGA and repaint with new land use classifications to accommodate allocation.
- Determine distribution of Unaffiliated UGA allocation by selecting grid cells within a $1 / 2$ mile buffer of principal arterial routes, and/or within Transportation Analysis Zones (TAZs) recommended by Technical Advisory Committee.
- Distribute balance to selected areas within Unaffiliated UGA (consult reference tools).
- If necessary, identify Activity Center areas within Unaffiliated UGA and repaint with new land use classifications to accommodate share of allocation.
- Rural Areas
- Identify and select a subset of Rural TAZs by the presence of Activity Centers and/or Technical Advisory Committee recommendations.
- Determine proportion of allocation to be assigned to Mixed Use areas within these TAZs by consulting INDEX planned land use maps.
- Record allocation - along with any geography-specific observations - on $\log$ sheet.
- Select and distribute growth to rural grid cells within selected TAZs in the order described above for Population and Employment distribution.
- Repaint grid cells within Activity Areas with new land use classifications if necessary to accommodate share of allocation.
- Distribute balance to rest of regional geography (consult reference tools).

# E.3. IMPERVIOUS SURFACE ESTIMATION METHODOLOGY USING INDEX TOOL GRID-CELL DATA 

This section explains the methodology used to develop impervious surface estimates used in Chapter 5.6 - Water Quality and Hydrology in the Environmental Impact Statement.

## Overview

Understanding the way growth was painted at the INDEX cell-level helps to understand impervious surface changes across the alternatives. Where possible, the alternatives were painted in a manner generally consistent with current land use and planning goals. This means that high levels of growth were painted in places with medium to high levels of existing activity and zoning, as measured by population, employment, and land use category. Conversely, lower levels of growth were assigned to places that had low levels of existing activity and zoning. For example, population and employment added to rural areas were allocated to cells near roads, with existing land use intensity higher than the average rural cell. In this way, the use of INDEX cell data does not lead to unrealistic interpretations of future land uses and partially avoids the inherent variability associated with painting a spatially detailed long-term growth pattern at a regional scale.

Little or no growth was painted in natural resource, rural, parks and open space areas. Impervious surface in these areas is currently low and remained low in all the alternatives. Due to the addition of growth in places with existing levels of population and employment, the impervious surface coverage for these places in the alternatives did not jump from a very low percentage to a very high percentage (i.e. from $0 \%$ impervious surface to above $30 \%$ ). Instead, places already approaching a threshold level of impervious coverage moved from just below $10 \%$ to just above $30 \%$.

Using this methodology, it takes relatively little growth to move a cell from a low to a high impervious surface category. One or fewer dwelling unit per acre in a residential area has an impervious surface coverage of around $10 \%$, and two to four dwelling units per acre has an impervious coverage of around $30 \%$. Higher density residential areas, with five to seven units per acre, have an average impervious surface coverage of about $40 \%$, while residential areas with over seven units per acre have impervious surface coverage of about $60 \%$. An ecologically relevant movement is from $10 \%$ to over $30 \%$, and the ease with which acreage is moved into a higher category underscores the need to remain sensitive to minor land use changes and the effect these changes have on our water resources.

A common technique used to estimate imperviousness is the use of satellite data to estimate the amount of land given over to rooftops, parking, roads, green space, etc. However, given the generalized nature of the INDEX data, it was not feasible to assign cells exact percentages of impervious surface coverage as determined by amount of roof, road, parking and lawn space; although the best available data is used to make an estimate as to what impervious characteristics various land uses may have in 2040. And, given that the VISION 2020 update is a visioning project that looks 35 years into the future, it was not necessary to use a methodology involving this level of specificity.

The method used was a combination of using the INDEX land use type impervious coverage percentages, and then refining the percentage based on the amount of population assigned to each INDEX 5.5 acre grid cell. This was done because of the wide range in population densities that might exist in any given grid cell, even within any given land use type category. The methodology involved translating population per grid in residential and mixed -use zones into an estimate of land use intensity, and therefore average impervious surface coverage. For uses such as commercial and industrial, the literature found little variation between differing densities of use and therefore these land uses were assigned a single impervious surface coverage percentage. A standard value was also assigned for tribal, military and government lands. These values and the resulting estimates are shown in the figures below.

A summary of the impervious coverage percentages assigned for INDEX land use categories are found in the following table.

IMPERVIOUS COVER (\%) ASSIGNED FOR LAND USE TYPESIDENSITY

| Land Use | Population per Grid Cell | Default (\%) |
| :--- | :---: | :---: |
| Vacant (Residential and Mixed) | 0 | 0 |
| Low Density (Residential and Mixed Use) | $>0$ and $<11.2$ | 10 |
| Medium Density (Residential and Mixed Use) | $>11.2$ and $<28$ | 30 |
| High Density (Residential and Mixed Use) | $>=28$ and $<39.1$ | 40 |
| Multifamily | $>39.1$ | 60 |
| Industrial | $\mathrm{N} / \mathrm{A}$ | 75 |
| Commercial | $\mathrm{N} / \mathrm{A}$ | 85 |
| Right of Way | $\mathrm{N} / \mathrm{A}$ | 80 |
| Government/Military | $\mathrm{N} / \mathrm{A}$ | 20 |
| Tribal | $\mathrm{N} / \mathrm{A}$ | 0 |
| Resource and other Undevelopable | $\mathrm{N} / \mathrm{A}$ | 0 |
